URL http://www.maa.org/pubs/monthly_nov97_toc.html. The authors employ Mathematica to extend earlier work of Bailey, Borwein, and Plouffe, [BBP97], done in 1995, but only just published, that discovered an amazing formula for \( \pi \) as a power series in \( 16^{-k} \), enabling any base-16 digit of \( \pi \) to be computed without knowledge of any prior digits. In this paper, Mathematica is used to find several simpler formulas having powers of \( 4^{-k} \). They also note that it has been proven that their methods cannot be used to exhibit similar formulas in powers of \( 10^{-k} \).

See the reproduction of results, and reanalysis, in [BBBR16], that reveals a flaw in the statistical analysis in this paper: Ganz used only a single blocksize in sampling digits, and that blocksize produces anomalous statistics.
