10.3 Complex Fourier Transform

A. Purpose

This subroutine computes Fourier transforms for complex data in up to 6 dimensions using the fast Fourier transform. The relation between values $z$ and Fourier coefficients $\zeta$ is defined by

$$z(j_1, j_2, \ldots, j_{ND}) = \sum_{k_1=0}^{N_1-1} \ldots$$

$$\sum_{k_{ND}=0}^{N_{ND}-1} \zeta(k_1, k_2, \ldots, k_{ND}) W^j_1^{i k_1} \ldots W^j_{ND}^{i k_{ND}}$$

where $N_t = 2^M(i)$, $W_t = e^{2\pi i/N_t}$, $0 \leq j_t$, $k_t \leq N_t - 1$, and $z$ and $\zeta$ are complex.

B. Usage

B.1 Program Prototype, Single Precision

COMPLEX A($N_1$, $N_2$, ..., $\geq N_{ND}$) [inout] $[N_k = 2^M(k)]$

REAL S($\geq \max(v_1, v_2, \ldots, v_{ND}) - 1$) [in] $[v_k = 2^M(k)-2]$

INTEGER M($\geq ND$), ND, MS

CHARACTER MODE($\geq ND$)

On the initial call set MS to 0 to indicate the array S() does not yet contain a sine table. Assign values to A(), MODE, M, and ND.

CALL SCFT(A, MODE, M, ND, MS, S)

A() will contain computed results. S() will contain the sine table used in computing the Fourier transform. MS may have been changed.

B.2 Argument Definitions

A() [inout] If the argument MODE selects analysis in all dimensions, A() contains values $z$ on entry, and Fourier coefficients $\zeta$ on exit. If MODE selects analysis in all dimensions, A() contains Fourier coefficients $\zeta$ on entry, and values $z$ on exit. When A() contains $z$, A($j_1 + 1$, $j_2 + 1$, ..., $j_{ND} + 1$) = $z(j_1, j_2, \ldots, j_{ND})$, and when A() contains $\zeta$, A($k_1 + 1$, $k_2 + 1$, ..., $k_{ND} + 1$) = $\zeta(k_1, k_2, \ldots, k_{ND})$, $0 \leq j_i$, $k_i \leq 2^M(i) - 1$, $i = 0, 1, \ldots, ND$.

MODE [in] The character MODE($k:k$) selects Analysis or Synthesis in the $k^{th}$ dimension. ‘A’ or ‘a’ selects Analysis, transforming $z$’s to $\zeta$’s. ‘S’ or ‘s’ selects Synthesis, transforming $\zeta$’s to $z$’s.

M() [in] Defines $N_k = 2^M(k)$, the number of complex data points in the $k^{th}$ dimension. Require $0 \leq M(k) \leq 30$ for all $k$. No action is taken in dimensions for which $M(k) = 0$.

ND [in] Number of dimensions. Require $1 \leq ND \leq 6$.

MS [inout] Gives the state of the sine table in S(). Let MS_in and MS_out denote the values of MS on entry and return respectively. If the sine table has not previously been computed, set MS_in = 0 or −1 before the call. Otherwise the value of MS_out from the previous call using the same S() array can be used as MS_in for the current call.

Certain error conditions described in Section E cause the subroutine to set MS_out = −2 and return. Otherwise, with $\max(M(i)) > 0$, the subroutine sets MS_out = $\max(M(1), M(2), \ldots, M(ND), MS_in)$.

If MS_out > $\max(2, MS_in)$, the subroutine sets NT = $2^{MS_out-2}$ and fills S() with NT − 1 sine values.

If MS_in = −1, the subroutine returns after the above actions, not transforming the data in A(). This is intended to allow the use of the sine table for data alteration before a subsequent Fourier transform, as discussed in Section G of Chapter 16.0.

S() [inout] When the sine table has been computed, S($j$) = $\sin \pi j/(2 \times NT)$, $j = 1, 2, \ldots, NT - 1$, see MS above.

B.3 Modifications for Double Precision

Change SCFT to DCFT and the REAL type statement to DOUBLE PRECISION. If it is available, one can change the COMPLEX type statement to DOUBLE PRECISION COMPLEX. For portability, (or out of necessity) one can change the COMPLEX statement to DOUBLE PRECISION and change the first dimension to be twice as big. The data should then be stored in A with the imaginary parts of the complex numbers following immediately after the real parts. This representation is compatible with the representation used in Fortran 90, and with most compilers that extend Fortran 77 to provide a double precision complex type.

C. Examples and Remarks

Estimate the spectral composition of

$$f(t) = [\sin 2\pi(t + 0.1) + 4 \cos 2\pi(\sqrt{2}t + 0.3)] + 0i$$
where we make the same assumptions and use the same $\Delta t$ and $N$ as in the example for SRFT1. Differences between the results given here and those obtained for SRFT1 are due to the use of sigma factors in SRFT1. (It is more efficient to use SRFT1 when $f$ is a real function. A real function was used here to show the effect of the sigma factors.) Note that the peaks are slightly sharper here than they are for SRFT1, but that as one leaves the peaks the coefficients do not tend to zero nearly as rapidly as when the sigma factors are used. The program to do these calculations and the results are given at the end of this chapter.

D. Functional Description
The multi-dimensional complex transform involves calling SFFT to compute one-dimensional complex transforms with respect to each dimension. For $ND = 1$, the formulas are given by Eqs. (9) and (10) in Chapter 16.0. For $ND \geq 1$, the formula for $z$ given $\zeta$ is given in Purpose above. More details can be found in [1].

References

E. Error Procedures and Restrictions
Require $1 \leq ND \leq 6$ and $0 \leq M(k) \leq 30$ for all $k$. MODE must have one of its allowed values. If any of these conditions are violated, the subroutine will issue an error message using the error processing procedures of Chapter 19.2 with severity level 2 to cause execution to stop. A return is made with $MS = -2$ instead of stopping if the statement “CALL ERMSET(-1)” is executed before calling this subroutine.

If the sine table does not appear to have valid data, an error message is printed, and the sine table and then the transform are computed.

F. Supporting Information
The source language is ANSI Fortran 77.
