Introduction to OpenMP
COSC 594

Piotr Luszczek

Innovative Computing Laboratory, University of Tennessee Knoxville

February 14, 2018

\(^1\)lushczek (at) icl.utk.edu
Outline

1. Introduction
2. Models
3. Syntax and Semantics
4. Individual Directives
5. Work Sharing
6. Synchronization Primitives
7. Memory Consistency Model Considerations
8. Runtime
9. Mutual Exclusion, Timing, and Environment
10. Conclusions, Summary, Further Reading
Acknowledgment

These slides are adapted from the Lawrence Livermore National Laboratory OpenMP Tutorial by Blaise Barney available at https://computing.llnl.gov/tutorials/openMP/
What is OpenMP?

- A language extension and an Application Program Interface (API) that may be used to explicitly direct multi-threaded, shared memory parallelism
- Comprises three primary API components
  - Compiler Directives
  - Runtime Library Routines
  - Environment Variables
- Portable
  - The API is specified for C/C++ and Fortran
  - Has been implemented for most major platforms including Unix/Linux platforms and Windows NT derivatives (Visual Studio 2012)
What is OpenMP? (continued)

- **Standardized**
  - Jointly defined and endorsed by a group of major computer hardware and software vendors
  - Still hoping for an ANSI standard
- **What does OpenMP stand for?**
  - Short version: OpenMulti-Processing
  - Long version: Open specifications for Multi-Processing via collaborative work between interested parties from the hardware and software industry, government and academia.
OpenMP is NOT

- Meant for **distributed memory** parallel systems (by itself)
- Necessarily implemented **identically** by all vendors
- Guaranteed to make the **most efficient** use of shared memory
- Required to **check** for data dependencies, data conflicts, race conditions, or deadlocks
- Required to check for code sequences that cause a program to be classified as non-conforming
- Meant to cover compiler-generated **automatic parallelization** and directives to the compiler to assist such parallelization
- Designed to guarantee that **input or output** to the same file is synchronous when executed in parallel
  - The programmer is responsible for **synchronizing** input and output.
History of OpenMP

- In the early 90’s, vendors of shared-memory machines supplied similar, directive-based, Fortran programming extensions.
- The user would augment a serial Fortran program with directives specifying which loops were to be parallelized.
- The compiler would be responsible for automatically parallelizing such loops across the SMP processors.
- Implementations were all functionally similar, but were divergent.
- First attempt at a standard was the draft for ANSIX3H5 in 1994. It was never adopted, largely due to waning interest as distributed memory machines became popular.
The OpenMP standard specification started in the spring of 1997, taking over where ANSI X3H5 had left off, as newer shared memory machine architectures started to become prevalent.

Led by the OpenMP Architecture Review Board (ARB). Original ARB members included: (Disclaimer: all partner names derived from the OpenMP web site)

- Compaq / Digital (acquired by HP)
- Hewlett-Packard Company (split into HP-E and HP-PC)
- Intel Corporation
- International Business Machines (IBM)
- Kuck & Associates, Inc. (KAI) acquired by Intel
- Silicon Graphics, Inc. (acquired by Rackable and now HPE)
- Sun Microsystems, Inc. (acquired by Oracle)
- U.S. Department of Energy ASCI program

OpenMP Release History

Ver. 5.0 expected late 2018/early 2019 with memory affinity extensions.
Goals of OpenMP

- Standardization
  - Provide a standard among a variety of shared memory architectures/platforms
- Lean and mean
  - Establish a simple and limited set of directives for programming shared memory machines
  - Significant parallelism can be implemented by using just 3 or 4 directives.
- Ease of Use
  - Provide capability to incrementally parallelize a serial program, unlike message-passing libraries which typically require an all or nothing approach
  - Provide the capability to implement both coarse-grain and fine-grain parallelism
- Portability
  - Supports Fortran (77, 90, 95, 2003, 2008); C and C++
  - Public forum for API and membership
OpenMP Programming Model

- Shared memory, thread-based parallelism
  - OpenMP is based upon the existence of multiple threads in the shared memory programming paradigm.
  - A shared memory process consists of multiple threads.
- Explicit Parallelism
  - OpenMP is an explicit (not automatic) programming model, offering the programmer full control over parallelization.
  - OpenMP uses the fork-join model of parallel execution.
- Compiler directive-based
  - Most OpenMP parallelism is specified through the use of compiler directives which are imbedded in C/C++ or Fortran source code.
- Nested parallelism support
  - The API provides for the placement of parallel constructs inside of other parallel constructs.
  - Implementations may or may not support this feature.
Fork-Join Model (aka BSP [1, 2])

All OpenMP programs begin as a single process: the master thread. The master thread executes sequentially until the first parallel region construct is encountered.

FORK: the master thread then creates a team of parallel threads.

The statements in the program that are enclosed by the parallel region construct are then executed in parallel among the team threads.

JOIN: When the team threads complete the statements in the parallel region construct, they synchronize and terminate, leaving only the master thread.
OpenMP specifies nothing about parallel I/O. This is particularly important if multiple threads attempt to read/write from/to the same file.

If every thread conducts I/O to a different file, the issues are not as significant.

It is entirely up to the programmer to ensure that I/O is conducted correctly within the context of a multi-threaded program.
OpenMP provides a relaxed-consistency and temporary view of thread memory (in their words). In other words, threads can cache their data and are not required to maintain exact consistency with real memory all of the time.

When it is critical that all threads view a shared variable identically, the programmer is responsible for insuring that the variable is FLUSHed by all threads as needed.

More on this later…
OpenMP Code Structure – **Fortran**

```fortran
PROGRAM HELLO
INTEGER VAR1, VAR2, VAR3
! Serial code
! . . .
! . . .
! Beginning of parallel section. Fork a team of threads.
! Specify variable scoping.
!$OMP PARALLEL PRIVATE(VAR1, VAR2) SHARED(VAR3)
! Parallel section executed by all threads
! . . .
! . . .
! All threads join master thread and disband
!$OMP END PARALLEL
! Resume serial code
! ...
END
```
OpenMP Code Structure – C/C++

#include <omp.h>

int main (void) {
    int var1, var2, var3;
    // Serial code
    // . . .
    // Beginning of parallel section. Fork a team of threads.
    // Specify variable scoping.
    #pragma omp parallel private(var1, var2) shared(var3)
    {
        // Parallel section executed by all threads
        // . . .
        // All threads join master thread and disband
    }
    // Resume serial code
    // . . .
}
If OpenMP Support is Missing …

- **Fortran** OpenMP directives are comments and will be ignored (library functions will be missing at link time).
- **C/C++** pragmas can be safely ignored by the compiler:

  GCC 7: `warning: ignoring #pragma omp parallel [-Wunknown-pragmas]`

- **C/C++** headers may be included conditionally:

  ```
  #if defined (_OPENMP)
  #include <omp.h>
  #endif
  ```
Fortran Directives Format

\(<\text{sentinel}\> \ <\text{directive-name}\> \ [\text{clause...}]\)

- All Fortran OpenMP directives must begin with a sentinel. The accepted sentinels depend on the type of Fortran source (see next two slides).
- A valid OpenMP directive must appear after the sentinel and before any clauses.
- Optional clauses can be in any order and repeated as necessary unless otherwise restricted.
- Example:

  \(!$OMP \text{ PARALLEL DEFAULT(SHARED) PRIVATE(BETA,PI)}\)
**Fortran Directives Format (continued)**

- **Fixed Form Source**
  - `$OMP C$OMP $OMP` are accepted sentinels and must start in column 1
  - All *Fortran* fixed form rules for line length, white space, continuation and comment columns apply for the entire directive line
  - Initial directive lines must have a space/zero in column 6.
  - Continuation lines must have a non-space/zero in column 6.

- **Free Form Source**
  - `$OMP` is the only accepted sentinel. Can appear in any column, but must be preceded by white space only.
  - All *Fortran* free form rules for line length, white space, continuation and comment columns apply for the entire directive line
  - Initial directive lines must have a space after the sentinel.
  - Continuation lines must have an ampersand as the last non-blank character in a line. The following line must begin with a sentinel and then the continuation directives.
## Fortran Directives Format

### General Rules
- Comments cannot appear on the same line as a directive
- Only one directive-name may be specified per directive
- **Fortran** compilers that are **OpenMP** enabled generally include a command line option that instructs the compiler to activate and interpret all **OpenMP** directives.
- Several **Fortran OpenMP** directives come in pairs and have the form shown below. The “end” directive is optional but advised for readability.

```fortran
!$OMP <directive> [structured block of code]
!$OMP end <directive>
```
C/C++ Directives Format

```c
#pragma omp <directive-name> [clause,...]
```

- New line at the end required and precedes the structured block that follows the directive

Example:

```c
#pragma omp parallel default(shared) private(beta,pi)
```
C/C++ Directives Format (continued)

- **General Rules:**
  - Case sensitive
  - Directives follow conventions of the C/C++ standards for compiler directives.
  - Only one directive-name may be specified per line.
  - Each directive applies to at most one succeeding statement, which must be a structured block.
  - Long directive lines can be “continued” on succeeding lines by escaping the newline character with a backslash ("\") at the end of a directive line.
Directive Scoping

- Static (Lexical) Extent
  - The code textually enclosed between the beginning and the end of a structured block following a directive.
  - The static extent of a directives does not span multiple routines or code files

- Orphaned Directive
  - An OpenMP directive that appears independently from another enclosing directive is said to be an orphaned directive. It exists outside of another directive’s static (lexical) extent.
  - Will span routines and possibly code files

- Dynamic Extent
  - The dynamic extent of a directive includes both its static (lexical) extent and the extents of its orphaned directives.
Directive Scoping Example – Fortran

PROGRAM TEST
...
!

$OMP PARALLEL
...
!

$OMP DO
DO I=...
...
CALL SUB1...
END DO
...
CALL SUB2
...
!

Directive Scoping Example – C/C++

```c
int main(void) {
    /* ... */
#pragma omp parallel
    { /* ... */
#pragma omp for
    for (int i = 0; i<N ;++i) {
        /* ... */
        fnct1();
    }
    /* ... */
    fnct2();
    /* ... */
}

void fnct1() {
    /* ... */
#pragma omp critical
    /* ... */
}

void fnct2() {
    /* ... */
#pragma omp sections
    { /* ... */
    }
    /* ... */
}
```

<table>

</tr>
</tbody>
</table>
PARALLEL Region Construct

- Block of code that will be executed by multiple threads
- Fundamental OpenMP parallel construct
- When a thread reaches a PARALLEL directive, it creates a team of threads and becomes the master of the team. The master is a member of that team and has thread number 0 within that team.
- Starting from the beginning of this parallel region, the code is duplicated and all threads will execute that code.
- There is an implied barrier at the end of a parallel section. Only the master thread continues execution past this point.
- If any thread terminates within a parallel region, all threads in the team will terminate, and the work done up until that point is undefined.
PARALLEL Region Syntax – Fortran

 !$OMP PARALLEL [clause ...]
   IF (scalar_logical_expression)
   PRIVATE (list)
   SHARED (list)
   DEFAULT (PRIVATE | FIRSTPRIVATE | SHARED | NONE)
   FIRSTPRIVATE (list)
   REDUCTION (operator: list)
   COPYIN (list)
   NUM_THREADS (scalar-integer-expression)

 block
 !$OMP END PARALLEL
#pragma omp parallel [clause ...]
  if (scalar_expression)
  private (list)
  shared (list)
  default (shared | none)
  firstprivate (list)
  reduction (operator: list)
  copyin (list)
  num_threads (integer-expression)
structured_block
PARALLEL Region – Number of Threads

The number of threads in a parallel region is determined by the following factors, in order of precedence:

1. Evaluation of the IF clause
2. Setting of the NUM_THREADS clause
3. Use of the omp_set_num_threads() library function
4. Setting of the OMP_NUM_THREADS environment variable
5. Implementation default – usually the number of cores on a node.

Threads are numbered from 0 (master thread) to N – 1
Use the `omp_get_nested()` library function to determine if nested parallel regions are enabled.

The two methods available for enabling nested parallel regions (if supported) are:

- The `omp_set_nested()` library routine
- Setting of the `OMP_NESTED` environment variable to TRUE

If not supported, a parallel region nested within another parallel region results in the creation of a new team, consisting of one thread, by default.
A parallel region must be a structured block that does not span multiple routines or code files.

- It is illegal to branch into or out of a parallel region.
- Only a single `IF` clause is permitted.
- Only a single `NUM_THREADS` clause is permitted.
PROGRAM HELLO
INTEGER NTHREADS, TID, OMP_GET_NUM_THREADS,
+ OMP_GET_THREAD_NUM
C Fork a team of threads with each thread having a private TID variable
!$OMP PARALLEL PRIVATE(TID)
C Obtain and print thread id
   TID = OMP_GET_THREAD_NUM()
   PRINT *, ’Hello World from thread = ’, TID
C Only master thread does this
   IF (TID .EQ. 0) THEN
      NTHREADS = OMP_GET_NUM_THREADS()
      PRINT *, ’Number of threads = ’, NTHREADS
   END IF
C All threads join master thread and disband
!$OMP END PARALLEL
END
PARALLEL Region Example – C/C++

#include <omp.h>

int main(void) {
    int nthreads, tid;

    /* Fork a team of threads with each thread having a private tid variable */
    #pragma omp parallel private(tid)
    {
        /* Obtain and print thread id */
        tid = omp_get_thread_num();
        printf ("Hello World from thread = %d\n", tid);
        /* Only master thread does this */
        if (tid == 0) {
            nthreads = omp_get_num_threads();
            printf("Number of threads = %d\n", nthreads);
        }
    }

    /* All threads join master thread and terminate */
}
Work-sharing Constructs

- A work-sharing construct divides the execution of the enclosed code region among the members of the team that encounter it.
- Work-sharing constructs do not launch new threads.
- There is no implied barrier upon entry to a work-sharing construct, however there is an implied barrier at the end of a work sharing construct.
- A work-sharing construct must be enclosed dynamically within a parallel region in order for the directive to execute in parallel.
- Work-sharing constructs must be encountered by all members of a team or none at all.
- Successive work-sharing constructs must be encountered in the same order by all members of a team.
Types of Work-sharing Constructs

- **DO/for**
  - Shares iterations of a loop across the team
  - Represents a type of “data parallelism”

- **SECTIONS**
  - Breaks work into separate, discrete sections
  - Each section is executed by a thread.
  - Can be used to implement a type of “functional parallelism”

- **SINGLE**
  - Serializes a section of code
Fortran DO Directive Syntax

$OMP DO [clause ...]
    SCHEDULE (type [,chunk])
    ORDERED
    PRIVATE (list)
    FIRSTPRIVATE (list)
    LASTPRIVATE (list)
    SHARED (list)
    REDUCTION (operator | intrinsic : list)
    COLLAPSE (n)
do_loop
$OMP END DO [ NOWAIT ]
C/C++ DO Directive Syntax

#pragma omp for [clause ...]
    schedule (type [,chunk])
    ordered
    private (list)
    firstprivate (list)
    lastprivate (list)
    shared (list)
    reduction (operator: list)
    collapse (n)
    nowait
for_loop
**SCHEDULE Clause**

Describes how iterations of the loop are divided among the threads in the team. The default schedule is implementation dependent.

**STATIC** Loop iterations are divided into pieces of size chunk and then statically assigned to threads. If chunk is not specified, the iterations are evenly (if possible) divided contiguously among the threads.

**DYNAMIC** Loop iterations are divided into pieces of size chunk, and dynamically scheduled among the threads; when a thread finishes one chunk, it is dynamically assigned another. The default chunk size is 1.

**GUIDED** For a chunk size of 1, the size of each chunk is proportional to the number of unassigned iterations divided by the number of threads, decreasing to 1. For a chunk size with value k (greater than 1), the size of each chunk is determined in the same way with the restriction that the chunks do not contain fewer than k iterations (except for the last chunk to be assigned, which may have fewer than k iterations). The default chunk size is 1.

**RUNTIME** The scheduling decision is deferred until runtime by the environment variable OMP_SCHEDULE. It is illegal to specify a chunk size for this clause.
**Other DO/for Clauses**

**NOWAIT/nowait**  If specified, then threads do not synchronize at the end of the parallel loop.

**ORDERED**  Specifies that the iterations of the loop must be executed as they would be in a serial program.

**COLLAPSE**  Specifies how many loops in a nested loop should be collapsed into one large iteration space and divided according to the schedule clause. The sequential execution of the iterations in all associated loops determines the order of the iterations in the collapsed iteration space.

Other clauses are described in detail later.
Fortran DO Directive Example

PROGRAM VEC_ADD_DO
INTEGER N, CHUNKSIZE, CHUNK, I
PARAMETER (N=1000, CHUNKSIZE=100)
REAL A(N), B(N), C(N)
!
! Some initializations
DO I = 1, N
   A(I) = I * 1.0
   B(I) = A(I)
END DO
CHUNK = CHUNKSIZE
!
!$OMP PARALLEL SHARED(A,B,C,CHUNK) PRIVATE(I)
!$OMP DO SCHEDULE(DYNAMIC,CHUNK)
   DO I = 1, N
      C(I) = A(I) + B(I)
   END DO
!$OMP END DO NOWAIT
!$OMP END PARALLEL
END
#include <omp.h>
#define CHUNKSIZE 100
#define N 1000
int main (void) {
    int i, chunk;
    float a[N], b[N], c[N];
    /* Some initializations */
    for (i=0; i < N; i++) a[i] = b[i] = i * 1.0;
    chunk = CHUNKSIZE;
#pragma omp parallel shared(a,b,c,chunk) private(i)
    {
        #pragma omp for schedule(dynamic,chunk) nowait
        for (i=0; i < N; i++) c[i] = a[i] + b[i];
    }
} /* end of parallel section */
SECTIONS Directive – Fortran Syntax

$OMP SECTIONS [clause ...]
  PRIVATE (list)
  FIRSTPRIVATE (list)
  LASTPRIVATE (list)
  REDUCTION (operator | intrinsic : list)
$OMP SECTION
  block
$OMP SECTION
  block
$OMP END SECTIONS [ NOWAIT ]
SECTIONS Directive – C/C++ Syntax

```c
#pragma omp sections [clause ...]
private (list)
firstprivate (list)
lastprivate (list)
reduction (operator: list)
nowait
{
#pragma omp section newline
    structured_block
#pragma omp section newline
    structured_block
}
```
PROGRAM VEC_ADD_SECTIONS
INTEGER N, I
PARAMETER (N=1000)
REAL A(N), B(N), C(N), D(N)
!
DO I = 1, N
A(I) = I * 1.5
B(I) = I + 22.35
END DO
!
OMP PARALLEL SHARED(A,B,C,D), PRIVATE(I)
!
OMP SECTIONS

OMP SECTION
DO I = 1, N
C(I) = A(I) + B(I)
END DO
!
OMP SECTION
DO I = 1, N
D(I) = A(I) * B(I)
END DO
!
OMP END SECTIONS NOWAIT
!
OMP END PARALLEL
END
int main (void) {
    int i; float a[N], b[N], c[N], d[N];
    for (i=0; i < N; i++) { /* Some initializations */
        a[i] = i * 1.5; b[i] = i + 22.35;
    }

    #pragma omp parallel shared(a,b,c,d) private(i)
    {
        #pragma omp sections nowait
        {
            #pragma omp section
            for (i=0; i < N; i++) c[i] = a[i] + b[i];
            #pragma omp section
            for (i=0; i < N; i++) d[i] = a[i] * b[i];
        } /* end of sections */
    } /* end of parallel section */
}
Questions for Thought (with Answers)

- What happens if the number of threads and the number of SECTIONs are different?

  It will work but is implementation-dependent.

- What if there are more threads than SECTIONs?

  It is implementation-dependent and some threads will not have any code to run.

- Fewer threads than SECTIONs?

  It is implementation-dependent and some threads will get more than one section.

- Which thread executes which SECTION?

  It is implementation-dependent and may not be guaranteed.
Questions for Thought (with Answers)

■ What happens if the number of threads and the number of SECTIONs are different?
  ■ It will work but is implementation-dependent.
■ What if there are more threads than SECTIONs?
Questions for Thought (with Answers)

   It is implementation-dependent and may not be guaranteed.
Synchronization Constructs

- Motivation: Consider a simple example where two threads on two different processors are both trying to increment a variable x at the same time (assume x is initially 0).

<table>
<thead>
<tr>
<th>THREAD 1:</th>
<th>THREAD 2:</th>
</tr>
</thead>
<tbody>
<tr>
<td>increment(x) {</td>
<td>increment(x) {</td>
</tr>
<tr>
<td>[x = x + 1;]</td>
<td>[x = x + 1;]</td>
</tr>
<tr>
<td>}</td>
<td>}</td>
</tr>
<tr>
<td>THREAD 1:</td>
<td>THREAD 2:</td>
</tr>
<tr>
<td>10 LOAD A, (x address)</td>
<td>10 LOAD A, (x address)</td>
</tr>
<tr>
<td>20 ADD A, 1</td>
<td>20 ADD A, 1</td>
</tr>
<tr>
<td>30 STORE A, (x address)</td>
<td>30 STORE A, (x address)</td>
</tr>
</tbody>
</table>

- The incrementation of x must be synchronized between the two threads to insure that the correct result is produced.

- **OpenMP** provides a variety of synchronization constructs that control how the execution of each thread proceeds relative to other team threads.
Synchronization Constructs

The CRITICAL directive specifies a region of code that must be executed by only one thread at a time.

<table>
<thead>
<tr>
<th></th>
<th>Fortran</th>
<th>C/C++</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>!$OMP CRITICAL [ name ] block</td>
<td>#pragma omp critical [ name ] structured_block</td>
</tr>
<tr>
<td></td>
<td>!$OMP END CRITICAL</td>
<td></td>
</tr>
</tbody>
</table>

If a thread is currently executing inside a CRITICAL region and another thread reaches that CRITICAL region and attempts to execute it, it will block until the first thread exits that CRITICAL region.

The optional name enables multiple different CRITICAL regions to exist.

Names act as global identifiers. Different CRITICAL regions with the same name are treated as the same region.

All unnamed CRITICAL regions are treated as the same region.
CRITICAL Directive Example

```c
#include <omp.h>
int main(void) {
    int x = 0;
    #pragma omp parallel shared(x)
    {
        #pragma omp critical
        x = x + 1;
        /* end of parallel region */
    }
    return 0;
}
```
Other Synchronization Constructs

- **MASTER directive** specifies a region that is to be executed only by the master thread.

  - All other threads on the team skip this section of code.

    - Fortran: `!$OMP MASTER`  
      - C/C++: `#pragma omp master`  

- **BARRIER directive** synchronizes all threads in the team.

  - When a BARRIER directive is reached, a thread will wait at that point until all other threads have reached that barrier. All threads then resume executing in parallel the code that follows the barrier.

    - Fortran: `!$OMP BARRIER`  
      - C/C++: `#pragma omp barrier`

- **ATOMIC directive** designates a given memory location for atomic update, rather than letting multiple threads attempt to write.

  - Applies only to a single, immediately following statement (only limited syntax supported).

    - Fortran: `!$OMP ATOMIC`  
      - C/C++: `#pragma omp atomic`
FLUSH Directive

- Identifies a synchronization point at which the implementation must provide a consistent view of memory.
- Thread-visible variables are written back to memory at this point.
- Necessary to instruct the compiler that a variable must be written to/read from the memory system, i.e. that a variable cannot be kept in a local CPU register.
  - Keeping a variable in a register in a loop is very common when producing efficient machine language code for a loop.
FLUSH Directive (continued)

**Fortran**  
\$OMP FLUSH (list)

**C/C++**  
#pragma omp flush (list)

- The optional list contains a list of named variables that will be flushed in order to avoid flushing all variables. For pointers in the list, the pointer itself is flushed, not the object to which it points.

- Implementations must ensure any prior modifications to thread-visible variables are visible to all threads after this point; i.e., compilers must restore values from registers to memory, hardware might need to flush write buffers, etc.

- The FLUSH directive is implied for the directives shown in the table below. The directive is not implied if a NOWAIT clause is present.
The FLUSH directive is implied for the directives shown in the table below. The directive is not implied if a NOWAIT clause is present.

ORDERED Directive

- Specifies that iterations of the enclosed loop will be executed in the same order as if they were executed on a serial processor.
- Threads will need to wait before executing their chunk of iterations if previous iterations haven’t completed yet.
- Used within a DO / for loop with an ORDERED clause.
- The ORDERED directive provides a way to "fine tune" where ordering is to be applied within a loop. Otherwise, it is not required.
- An ORDERED directive can only appear in the dynamic extent of the following directives:
  - **Fortran** DO or PARALLEL DO
  - **C/C++** for or parallel for
- Only one thread is allowed in an ordered section at any time.
- It is illegal to branch into or out of an ORDERED block.
- An iteration of a loop must not execute the same ORDERED directive more than once, and it must not execute more than one ORDERED directive.
- A loop that contains an ORDERED directive must be a loop with an ORDERED clause.
ORDERED Directive Syntax

**Fortran**

`!$OMP DO ORDERED [clauses...]`
(loop region)
`!$OMP ORDERED`
(block)
`!$OMP END ORDERED`
(end of loop region)
`!$OMP END DO`

**C/C++**

`#pragma omp for ordered [clauses...]`
(loop region)
`#pragma omp ordered structured_block`
(endo of loop region)
#include <stdio.h>
#include <omp.h>

static float a[1000], b[1000], c[1000];

void test(int first, int last) {
    int i;
    #pragma omp for schedule(static) ordered
    for (i = first; i <= last; ++i) {
        /* Do something here. */
        if (i % 2) {
            #pragma omp ordered
            printf ("test%d iteration\n", i);
        }
    }
}

void test2(int iter) {
    #pragma omp ordered
    printf ("test2%d iteration\n", iter);
}

int main(void) {
    int i;
    #pragma omp parallel
    {
        test(1, 8);
        #pragma omp for ordered
        for (i = 0; i < 5; i++)
            test2(i);
    }
}
Data Scope Attribute Clauses

- Also called data sharing attribute clauses
- Because OpenMP is based upon the shared memory programming model, most variables are shared by default.
- Global variables include:
  - **Fortran**: COMMON blocks, SAVE variables, MODULE variables
  - **C/C++**: File scope variables, static
- Private variables include:
  - Loop index variables
  - Stack variables in subroutines called from parallel regions
  - **Fortran**: Automatic variables within a statement block
- Clauses used to explicitly define how variables should be scoped include:
  - PRIVATE
  - SHARED
  - FIRSTPRIVATE
  - LASTPRIVATE
  - DEFAULT
  - REDUCTION
  - COPYIN
Data Scope Attribute Clauses (continued)

- Used in conjunction with several directives (PARALLEL, DO/for, and SECTIONS) to control the scoping of enclosed variables.
- Provide the ability to control the data environment during execution of parallel constructs.
- Define how and which data variables in the serial section of the program are transferred to the parallel sections of the program (and back).
- Define which variables will be visible to all threads in the parallel sections and which variables will be privately allocated to all threads.
- Effective only within their lexical/static extent.
PRIVATE and SHARED Clauses

- **PRIVATE Clause**
  - Declares variables in its list to be private to each thread
  - A new object of the same type is declared once for each thread in the team.
  - All references to the original object are replaced with references to the new object.
  - Variables declared PRIVATE should be assumed to be uninitialized for each thread.

- **SHARED Clause**
  - Declares variables in its list to be shared among all threads in the team
  - A shared variable exists in only one memory location and all threads can read or write to that address
  - It is the programmer’s responsibility to ensure that multiple threads properly access SHARED variables (such as via CRITICAL sections)
FIRSTPRIVATE and LASTPRIVATE Clauses

- FIRSTPRIVATE Clause
  - Combines the behavior of the PRIVATE clause with automatic initialization of the variables in its list.
  - Listed variables are initialized according to the value of their original objects prior to entry into the parallel or work-sharing construct.

- LASTPRIVATE Clause
  - Combines the behavior of the PRIVATE clause with a copy from the last loop iteration or section to the original variable object.
  - The value copied back into the original variable object is obtained from the last (sequentially) iteration or section of the enclosing construct.
  - For example, the team member that executes the final iteration for a DO section, or the team member that executes the last SECTION of a SECTIONS context, performs the copy with its own values.
PRIVATE Variables Example

```c
int main(void) {
    int A = 10;
    int B, C;
    int n = 20;

    #pragma omp parallel
    {
        #pragma omp for private(i) firstprivate(A) lastprivate(B)
        for (int i=0; i < n; i++) {
            /* .... */
            B = A + i; /* A undefined unless declared firstprivate */
            /* .... */
        }
        C = B; /* B undefined unless declared lastprivate */
    } /* end of parallel region */
}
```
DEFAULT Clause

- Allows the user to specify a default scope for all variables in the lexical extent of any parallel region
- Specific variables can be exempted from the default using the PRIVATE, SHARED, FIRSTPRIVATE, LASTPRIVATE, and REDUCTION clauses.
- The C/C++ OpenMP specification does not include private or firstprivate as a possible default. However, actual implementations may provide this option.
- Using NONE as a default requires that the programmer explicitly scope all variables.

| Fortran          | DEFAULT (PRIVATE | FIRSTPRIVATE | SHARED | NONE) |
|------------------|------------------|
| C/C++            | default (shared | none)        |
REDUCTION Clause

- Performs a reduction on the variables that appear in its list.
- A private copy for each list variable is created for each thread. At the end of the reduction, the reduction operator is applied to all private copies of the shared variable, and the final result is written to the global shared variable.

Syntax:

**Fortran**

```
REDUCTION (operator | intrinsic: list)
```

**C/C++**

```
reduction (operator: list)
```
REDUCTION Clause Example – Fortran

PROGRAM DOT_PRODUCT
INTEGER N, CHUNKSIZE, CHUNK, I
PARAMETER (N=100, CHUNKSIZE=10)
REAL A(N), B(N), RESULT

! Some initializations
DO I = 1, N
   A(I) = I * 1.0 ; B(I) = I * 2.0
END DO
RESULT = 0.0
CHUNK = CHUNKSIZE

!$OMP PARALLEL DO DEFAULT(SHARED) PRIVATE(I)
!$OMP& SCHEDULE(STATIC,CHUNK) REDUCTION(+:RESULT)
DO I = 1, N
   RESULT = RESULT + (A(I) * B(I))
END DO
!$OMP END PARALLEL DO NOWAIT
PRINT *, 'Final Result= ', RESULT
END
#include <omp.h>

int main (void) {
    int i, n = 100, chunk = 10;
    float a[100], b[100], result = 0.0;

    /* Some initializations */
    for (i=0; i < n; i++) {
        a[i] = i * 1.0;
        b[i] = i * 2.0;
    }

    #pragma omp parallel for default(shared) private(i) \ 
    schedule(static,chunk) reduction(+:result)
    for (i=0; i < n; i++)
        result += (a[i] * b[i]);
    printf ("Final result= %f\n",result);
}

THREADPRIVATE Directive

- Used to make global file scope variables (C/C++) or common blocks (Fortran) local and persistent to a thread through the execution of multiple parallel regions.
- Must appear after the declaration of listed variables/common blocks.
- Each thread then gets its own copy of the variable/common block, so data written by one thread is not visible to other threads.
- On first entry to a parallel region, data in THREADPRIVATE variables and common blocks should be assumed undefined, unless a COPYIN clause is specified in the PARALLEL directive.
- THREADPRIVATE variables differ from PRIVATE ones because they are able to persist between different parallel sections of a code.
- Data in THREADPRIVATE objects is guaranteed to persist only if the dynamic threads mechanism is ”turned off” and the number of threads in different parallel regions remains constant. The default setting of dynamic threads is undefined.

<table>
<thead>
<tr>
<th>Language</th>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fortran</td>
<td>!$OMP THREADPRIVATE (/cb/, ...)</td>
</tr>
<tr>
<td>C/C++</td>
<td>#pragma omp threadprivate (list)</td>
</tr>
</tbody>
</table>
THREADPRIVATE Example – Fortran

PROGRAM THREADPRIV
INTEGER A, B, I, TID, OMP_GET_THREAD_NUM ; REAL*4 X
COMMON /C1/ A

!$OMP THREADPRIVATE(/C1/, X)
C ** Explicitly turn off dynamic threads **
   CALL OMP_SET_DYNAMIC(.FALSE.)
   PRINT *, ’1st Parallel Region:

!$OMP PARALLEL PRIVATE(B, TID)
   TID = OMP_GET_THREAD_NUM ()
   A = TID ; B = TID ; X = 1.1 * TID + 1.0
   PRINT *, ’Thread’,TID,: A,B,X=’,A,B,X

!$OMP END PARALLEL
   PRINT *,’Master thread doing serial work here’, ’2nd Parallel Region: ’

!$OMP PARALLEL PRIVATE(TID)
   TID = OMP_GET_THREAD_NUM ()
   PRINT *, ’Thread’,TID,: A,B,X=’,A,B,X

!$OMP END PARALLEL
END
#include <omp.h>

int a, b, i, tid; float x;

#pragma omp threadprivate(a, x)
int main (void) {
    omp_set_dynamic(0); /* Explicitly turn off dynamic threads */
    printf ("1st Parallel Region:\n");
    #pragma omp parallel private(b,tid)
    {
        tid = omp_get_thread_num(); a = tid; b = tid; x = 1.1 * tid + 1.0;
        printf ("Thread %d: a,b,x= %d %d %f\n",tid,a,b,x);
    } /* end of parallel region */
    printf ("Master thread doing serial work here\n");
    printf ("2nd Parallel Region: \n");
    #pragma omp parallel private(tid)
    {
        tid = omp_get_thread_num();
        printf ("Thread %d: a,b,x= %d %d %f\n",tid,a,b,x);
    } /* end of parallel section */
}
COPYIN Clause

- Provides a means for assigning the same value to THREADPRIVATE variables for all threads in the team.
- List contains the names of variables to copy. In Fortran, the list can contain both the names of common blocks and named variables.
- The master thread variable is used as the copy source. The team threads are initialized with its value upon entry into the parallel construct.

<table>
<thead>
<tr>
<th>Fortran</th>
<th>COPYIN (list)</th>
</tr>
</thead>
<tbody>
<tr>
<td>C/C++</td>
<td>copyin (list)</td>
</tr>
</tbody>
</table>
**Runtime Library Routines**

- The **OpenMP** standard defines an API for library calls that perform a variety of functions:
  - Query the number of threads/processors, set number of threads to use
  - General purpose locking routines (semaphores)
  - Portable wall clock timing routines
  - Set execution environment functions: nested parallelism, dynamic adjustment of threads.
  - For **C/C++**, it may be necessary to specify the include file "omp.h".

Note: Your implementation may or may not support nested parallelism and/or dynamic threads. If nested parallelism is supported, it is often only nominal, in that a nested parallel region may only have one thread.
OMP_SET_NUM_THREADS()

- Sets the number of threads that will be used in the next parallel region
- Must be a positive integer
- Can only be called from serial portion of the code
- Has precedence over the OMP_NUM_THREADS environment variable

<table>
<thead>
<tr>
<th>Fortran</th>
<th>SUBROUTINE OMP_SET_NUM_THREADS(integer)</th>
</tr>
</thead>
<tbody>
<tr>
<td>C/C++</td>
<td>#include &lt;omp.h&gt;</td>
</tr>
<tr>
<td></td>
<td>void omp_set_num_threads(int num_threads)</td>
</tr>
</tbody>
</table>
OMP_GET_NUM_THREADS() and OMP_GET THREAD_NUM()

OMP_GET_NUM_THREADS()
- Returns the number of threads that are currently in the team executing the parallel region from which it is called.

OMP_GET_THREAD_NUM()
- Returns the thread number of the thread, within the team, making this call. This number will be between 0 and OMP_GET_NUM_THREADS-1. The master thread of the team is thread 0.
- If called from a nested parallel region, or a serial region, this function will return 0.

**Fortran**

| INTEGER FUNCTION OMP_GET_NUM_THREADS() |
| INTEGER FUNCTION OMP_GET_THREAD_NUM() |

**C/C++**

```
#include <omp.h>
int omp_get_num_threads(void)
int omp_get_thread_num(void)
```
OMP_GET_MAXTHREADS()

- Returns the maximum value that can be returned by a call to the OMP_GET_NUM_THREADS function
- Generally reflects the number of threads as set by the OMP_NUM_THREADS environment variable or the OMP_SET_NUM_THREADS() library routine.
- May be called from both serial and parallel regions of code

**Fortran**

`INTEGER FUNCTION OMP_GET_MAXTHREADS()
`  

**C/C++**

```c
#include <omp.h>
int omp_get_max_threads(void)
```
OMP_GET_THREAD_LIMIT() and OMP_GET_NUM_PROCS()

- **OMP_GET_THREAD_LIMIT()**
  - New with OpenMP 3.0
  - Returns the maximum number of OpenMP threads available to a program

- **OMP_GET_NUM_PROCS()**
  - Returns the number of processors that are available to the program

### Fortran

<table>
<thead>
<tr>
<th>INTEGER FUNCTION OMP_GET_THREAD_LIMIT()</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER FUNCTION OMP_GET_NUM_PROCS()</td>
</tr>
</tbody>
</table>

### C/C++

```c
#include <omp.h>
int omp_get_thread_limit(void)
int omp_get_num_procs(void)
```
**OMP_IN_PARALLEL()**

- May be called to determine if the section of code currently executing is parallel or not.
- For **Fortran**, this function returns `.TRUE.` if it is called from the dynamic extent of a region executing in parallel, and `.FALSE.` otherwise. For **C/C++**, it will return a non-zero integer if parallel, and zero otherwise.

<table>
<thead>
<tr>
<th><strong>Fortran</strong></th>
<th>LOGICAL FUNCTION OMP_IN_PARALLEL()</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>C/C++</strong></td>
<td><code>#include &lt;omp.h&gt;</code></td>
</tr>
<tr>
<td></td>
<td><code>int omp_in_parallel(void)</code></td>
</tr>
</tbody>
</table>
OMP_SET_DYNAMIC()

- Enables or disables dynamic adjustment (by the run time system) of the number of threads available for execution of parallel regions.
- For Fortran, if called with .TRUE. then the number of threads available for subsequent parallel regions can be adjusted automatically by the run-time environment. If called with .FALSE., dynamic adjustment is disabled.
- For C/C++, if dynamic_threads evaluates to non-zero, then the mechanism is enabled, otherwise it is disabled.
- The OMP_SET_DYNAMIC subroutine has precedence over the OMP_DYNAMIC environment variable.
- The default setting is implementation dependent.
- Must be called from a serial section of the program.

**Fortran**

```fortran
SUBROUTINE OMP_SET_DYNAMIC(scalar_logic_expr)
```

**C/C++**

```c
#include <omp.h>
void omp_set_dynamic(int dynamic_threads)
```
OMP_GET_DYNAMIC()

- Used to determine if dynamic thread adjustment is enabled or not
- For **Fortran**, this function returns `.TRUE.` if dynamic thread adjustment is enabled, and `.FALSE.` otherwise.
- For **C/C++**, non-zero will be returned if dynamic thread adjustment is enabled, and zero otherwise.

<table>
<thead>
<tr>
<th></th>
<th>Fortran</th>
<th>C/C++</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Function</strong></td>
<td>LOGICAL FUNCTION OMP_GET_DYNAMIC()</td>
<td>#include &lt;omp.h&gt;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>int omp_get_dynamic(void)</td>
</tr>
</tbody>
</table>
OMP_SET_NESTED()

- Used to enable or disable nested parallelism
- For Fortran, calling this function with .FALSE. will disable nested parallelism, and calling with .TRUE. will enable it.
- For C/C++, if nested evaluates to non-zero, nested parallelism is enabled; otherwise it is disabled.
- The default is for nested parallelism to be disabled.
- This call has precedence over the OMP_NESTED environment variable.

<table>
<thead>
<tr>
<th>Fortran</th>
<th>SUBROUTINE OMP_SET_NESTED(scalar_logical_expr)</th>
</tr>
</thead>
<tbody>
<tr>
<td>C/C++</td>
<td>#include &lt;omp.h&gt;</td>
</tr>
<tr>
<td></td>
<td>void omp_set_nested(int nested)</td>
</tr>
</tbody>
</table>
OMP_GET_NESTED()  

- Used to determine if nested parallelism is enabled or not.
- For **Fortran**, this function returns .TRUE. if nested parallelism is enabled, and .FALSE. otherwise.
- For **C/C++**, non-zero will be returned if nested parallelism is enabled, and zero otherwise.

<table>
<thead>
<tr>
<th><strong>Fortran</strong></th>
<th>LOGICAL FUNCTION OMP_GET_NESTED()</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>C/C++</strong></td>
<td>#include &lt;omp.h&gt; int omp_get_nested(void)</td>
</tr>
</tbody>
</table>
Locking Routines

- **OMP_INIT_LOCK()**
  - Initializes a lock associated with the lock variable
  - The initial state is unlocked.
  - For **Fortran**, `var` must be an integer large enough to hold an address, such as `INTEGER *8` on 64-bit systems.

  ```fortran
  SUBROUTINE OMP_INIT_LOCK(var)
  C/C++
  #include <omp.h>
  void omp_init_lock(omp_lock_t *lock)
  ```

- **OMP_DESTROY_LOCK()**
  - Disassociates the given lock variable from any locks

  ```fortran
  SUBROUTINE OMP_DESTROY_LOCK(var)
  C/C++
  #include <omp.h>
  void omp_destroy_lock(omp_lock_t *lock)
  ```
Locking Routines (continued)

- **OMP_SET_LOCK()**
  - Forces the executing thread to wait until the specified lock is available

<table>
<thead>
<tr>
<th>Fortran</th>
<th>C/C++</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUBROUTINE OMP_SET_LOCK(var)</td>
<td>#include &lt;omp.h&gt;</td>
</tr>
<tr>
<td></td>
<td>void omp_set_lock(omp_lock_t *lock)</td>
</tr>
</tbody>
</table>

- **OMP_UNSET_LOCK()**
  - Releases the lock from the executing thread

- **OMP_TEST_LOCK()**
  - Attempts to set a lock, but does not block if the lock is unavailable
OMP\_GET\_WTIME()

- Provides a portable wall clock timing routine
- Returns a double-precision floating point value equal to the number of elapsed seconds since some point in the past
- Usually used in pairs with the value of the first call subtracted from the value of the second call to obtain the elapsed time for a block of code
- Designed to be per thread times, and therefore may not be globally consistent across all threads in a team

### Fortran

```
DOUBLE PRECISION FUNCTION OMP\_GET\_WTIME()
```

### C/C++

```
#include <omp.h>

double omp_get_wtime(void)
```
OpenMP Environment Variables

- **OMP_SCHEDULE**
  - Applies only to DO, PARALLEL DO (Fortran) and for, parallel for (C/C++) directives which have their schedule clause set to RUNTIME. The value of this variable determines how iterations of the loop are scheduled on processors.
  - For example:
    
    ```
    setenv OMP_SCHEDULE "guided, 4"
    setenv OMP_SCHEDULE "dynamic"
    ```

- **OMP_NUM_THREADS**
  - Sets the number of threads to use during execution
  - For example:
    
    ```
    setenv OMP_NUM_THREADS 8
    ```
OpenMP Environment Variables (cont.-d)

- **OMP_DYNAMIC**
  - Enables or disables dynamic adjustment of the number of threads available for execution of parallel regions
  - Valid values are TRUE or FALSE.
  - For example:
    ```
    setenv OMP_DYNAMIC TRUE
    ```

- **OMP_NESTED**
  - Enables or disables nested parallelism
  - Valid values are TRUE or FALSE.
  - For example:
    ```
    setenv OMP_NESTED TRUE
    ```
Thread Stack Size

- The OpenMP standard does not specify how much stack space a thread should have. Consequently, implementations will differ in the default thread stack size.

- Default thread stack size can be easy to exhaust. It can also be non-portable between compilers.

- Threads that exceed their stack allocation may or may not seg fault. An application may continue to run while data is being corrupted.

- Statically linked codes may be subject to further stack restrictions.

- A user’s login shell may also restrict stack size.

- May need to increase thread stack size. How to do this is system-dependent.
Performance Expectations

- One might expect to get an $N$ times speedup when running a program parallelized using OpenMP on an $N$ processor/core platform. However, this is seldom the case due to the following reasons:
  - A large portion of the program may not be parallelized by OpenMP, which means that the theoretical upper limit of speedup is limited according to Amdahl’s law.
  - $N$ processors in a SMP may have $N$ times the computation power, but the memory bandwidth usually does not scale up $N$ times. Quite often, the original memory path is shared by multiple processors and performance degradation may be observed when they compete for the shared memory bandwidth.
  - Many other common problems affecting the final speedup in parallel computing also apply to OpenMP, such as load balancing and synchronization overhead.
